List Comprehensions: Takeaways ⤴

Syntax

ENUMERATE

- To iterate over multiple lists in tandem:

```python
animals = ["Dog", "Tiger", "SuperLion", "Cow", "Panda"]

viciousness = [1, 5, 10, 10, 1]

for animal in animals:

    print("Animal")

    print(animal)

    print("Viciousness")
```

- To add columns to list of lists:

```python
door_count = [4, 4]

cars = [

        ["black", "honda", "accord"],

        ["red", "toyota", "corolla"]

        ]

for i, car in enumerate(cars):

    car.append(door_count[i])
```

LIST COMPREHENSIONS

- Before condensing the loop:

```python
animals = ["Dog", "Tiger", "SuperLion", "Cow", "Panda"]

animal_lengths = []

for animal in animals:

    animal_lengths.append(len(animal))
```

- After condensing the loop using a list comprehension:

```
animal_lengths = [len(animal) for animal in animals]
```

NONE OBJECT

- To indicate that a variable has no value, use the None object:

```
values = [-50, -80, -100]

max_value = None

for i in values:

    if max_value is None or i > max_value:

        max_value = i
```

COMPARING WITH NONE

- Joining two Boolean statements:

```
a = None

b = a is None or a > 10
```

THE ITEMS METHOD

- To access the keys and values of a dictionary, use the items() method:

```
fruits = {

    "apple": 2,

    "orange": 5,

    "melon": 10

}

for fruit, rating in fruits.items():

    print(rating)
```

Concepts

- To loop through multiple lists, use the **enumerate()** function. Enumerate adds a counter to an iterable, resulting in a tuple.
- To condense a for loop into one line, use a **list comprehension**. A list comprehension is a more concise way of iterating over multiple values in a list.
- An easy way of accessing a dictionaries keys and values is the **items** method.
